SYMBOLS AND NOTATIONS

1. *Character of the Earthquake*—
 I. Perceptible. II. Moderately strong. III. Strong.
 d (terrae motus domesticus) Local shock (origin less than 100 kilometers distant).
 v (terrae motus vicinus) Near shock (origin from 100 to 1,000 kilometers distant).
 r (terrae motus remotus) Distant shock (origin from 1,000 to 5,000 kilometers distant).
 u (terrae motus ultimus) Very distant shock or teleseism (origin more than 5,000 kilometers distant).

2. *Phases of the Seismogram*—
 P (undae primae) Normal first phase, or first preliminary tremors (longitudinal).
 P' First preliminary tremors which have penetrated the core of the earth.
 PR_n Waves n times reflected at the earth's surface.
 S (undae secundae) Second phase, or second preliminary tremors (transverse).
 SR_n Waves n times reflected at the earth's surface.
 PS Waves changed from longitudinal to transverse oscillation or vice versa through reflection at the earth's surface.
 PPS Waves twice reflected at the earth's surface, having been longitudinal on two branches of the path and transverse on one branch.

In general a bar over two letters denoting types of waves indicates refraction. The subscript _c denotes the boundary at about 2900 km. depth between the metallic core and the middle shell which surrounds it. Thus:

$\overline{S.P.S}$ Waves which have penetrated the core, having been transverse before entering and after leaving the core, and longitudinal within the core.

$\overline{P_c P_c P_c P_c}$ Waves refracted at the core boundary into the core, reflected once at this boundary while within the core and again refracted out of the core, having remained longitudinal on all branches of the path.

L (undae longae) Long waves at the beginning of the surface phase.
 M (undae maximae) Shorter and more regular waves of large amplitude in the surface phase.

M_n Greatest motion in the surface phase.

C (coda) Tail or end portion.

F (finis) End of discernible movement.

\overline{P} For local earthquakes a special notation is used:
 The longitudinal wave which has traveled its whole path in the surface layer or crust of the earth.

\overline{S} The transverse wave which has traveled its whole path in the surface layer of the earth.

In general R₁ denotes reflection once at the lower (inferior) surface of the earth's crust. R₂ denotes reflection twice at this surface. R_n indicates reflection at the upper (superior) surface of the crust, i.e., the surface of the earth. Thus, e.g.:

R₁₂ $\overline{P_3S_2}$ A wave in the earth's crust which has been reflected twice at the lower surface, having been longitudinal on two branches of its path and transverse on two branches.

3. *Nature of the Motion*—

i (impetus) Sudden beginning of the motion.

e (emersio) Gradual beginning of the motion.

T (period) Time of one complete oscillation.

A Amplitude of the earth motion, measured from the median line in microns ($\mu = \frac{1}{1000}$ mm.) + toward the north, east, or zenith, - toward the south, west, or nadir.

A_E E-W component of A.

A_N N-S component of A.

A_Z Vertical component of A.

4. *Time*—

O (origin) Time of shock at point of origin.

THE BERKELEY STATION

CONSTANTS

Latitude and longitude of the center of the seismographic room:

$\varphi = 37^\circ 52' 15.9''$ N. Lat.

$\lambda = 122^\circ 15' 36.6''$ W. from Greenwich.

Time. All determinations are reduced to Greenwich mean civil time.

Altitude, 85.4 meters (280 feet) above mean sea level.

THE LICK OBSERVATORY STATION

CONSTANTS

CONSTANTS OF THE STATION

Latitude and longitude of the center of the seismographic room:

$\varphi = 37^\circ 20' 24.5''$ N. Lat.
 $\lambda = 121^\circ 38' 34''$ W. from Greenwich.

Time. All determinations are reduced to Greenwich mean civil time.

Altitude, 1281.7 meters (4202.25 feet) above mean sea level.

THE INTERPRETATION OF THE DIRECTION OF
EARTH MOTION IN TERMS OF THE DIRECTION
OF MOTION OF THE MASS OF THE
SEISMOGRAPH

In the bulletins of the Berkeley Station and the Lick Observatory Station previous to about 1921, it was assumed that when the earth under the station moved, the masses of the seismographs, on account of their inertia, showed a relative motion in the direction opposite to that of the earth motion.

In the bulletins beginning about 1921 (the exact number is not known to the writer) this interpretation was abandoned for the horizontal components, the assumption being made for these that the masses acted in response to apparent tilt, thus showing a relative motion in the same direction as the earth motion. The older interpretation was retained for the vertical component.

In this issue of the bulletin we return to the earlier interpretation that the masses as a result of their inertia show a motion relative to their supports which is in a direction opposite to that of the earth motion.

This latter interpretation has seemed more satisfactory in the cases of a number of earthquakes which have been studied recently.
