#### 407

#### SYMBOLS AND NOTATIONS

#### 1. Character of the Earthquake-

I. Perceptible. II. Moderately strong. III. Strong.

d (terrae motus domesticus) Local shock (origin less than 100 kilo-

meters distant).

v (terrae motus vicinus) Near shock (origin from 100 to 1,000

kilometers distant).

r (terrae motus remotus) Distant shock (origin from 1,000 to

5,000 kilometers distant).

u (terrae motus ultimus) Very distant shock or teleseism (origin

more than 5,000 kilometers distant).

#### 2. Phases of the Seismogram-

P (undae primae) First phase, or first preliminary tremors.

PR<sub>n</sub> Waves n-times reflected at the earth's surface.

S (undae secundae) Second phase, or second preliminary tremors.

SR<sub>n</sub> Waves n-times reflected at the earth's surface.

PS Waves changed from longitudinal to transverse

oscillation, or vice versa, through reflection

at the earth's surface.

L (undae longae) Long waves, chief phase, or principal part.

M(undae maximae) Greatest motion in the chief phase.

C (coda) Tail or end portion.

F (finis) End of discernible movement.

#### 3. Nature of the Motion-

i (impetus) Sudden beginning of the motion.
e (emersio) Gradual beginning of the motion

e (emersio) Gradual beginning of the motion.

T (period) Time of one complete oscillation.

A Amplitude of the motion, measured from the median

line in microns ( $\mu = 1/1000$  mm.).

A<sub>E</sub> E-W component of A.

A<sub>N</sub> N-S component of A.

Av Vertical component of A.

#### 4. Time-

O (origin) Time of shock at point of origin.

#### THE BERKELEY STATION

#### CONSTANTS

Latitude and longitude of the center of the seismographic room:

 $\phi = 37^{\circ} 52' 15.''9$  N. Lat.  $\lambda = 122^{\circ} 15' 36.''6$  W. from Greenwich.

Time. All determinations are reduced to Greenwich mean civil time.

Altitude, 85.4 meters (280 feet) above mean sea-level.

#### CONSTANTS OF THE SEISMOGRAPHS

|                                       | Period | Magnif. | Damping |
|---------------------------------------|--------|---------|---------|
| Bosch-Omori Seismograph N-S component | 15°    | 80      | 8-1     |
| Bosch-Omori Seismograph E-W component | 15*    | 80      | 8-1     |
| Wiechert Seismograph Vert. component  | 6*     | 80      | 8-1     |
| Omori Tromometer N-S component        | 2ª     | 60      | *****   |
| Omori Tromometer E-W component        | 2.5*   | 60      | 2,,,,,  |
| Marvin Strong-motion Seismograph—     |        |         |         |
| E-W component                         | 6.5*   | 5.8     | 1.3-1   |
| N-S component                         | 6.5ª   | 5.1     | 1.4-1   |

### THE LICK OBSERVATORY STATION

#### CONSTANTS

#### CONSTANTS OF THE STATION

Latitude and longitude of the center of the seismographic room:

 $\phi = 37^{\circ} 20' 24.''5 \text{ N. Lat.}$  $\lambda = 121^{\circ} 38' 34'' \text{ W. from Greenwich.}$ 

Time. All determinations are reduced to Greenwich mean civil time.

Altitude, 1281.7 meters (4202.25 feet) above mean sea-level.

## DISCUSSION OF PARTICULAR SHOCKS

THE INGLEWOOD EARTHQUAKE OF JUNE 22, 1920†

The earthquake at Inglewood, California, on June 22, 1920, has been investigated in the field by Dr. Stephen Taber.\* It was hoped that a study of the seismograms, in connection with his field determination of epicenter and time of origin, would contribute to our knowledge of the hodograph for such epicentral distances. But the seismograms proved to be somewhat disappointing in several respects: On all components, at both the Lick and Berkeley stations, the beginning of the first preliminary tremor takes the form of a very gradual emersio, so that a determination of the exact time of arrival of the first waves is impossible. Changes of character which might be consistently interpreted as the inception of subsequent phases are ill-defined and sometimes entirely wanting. Taber does not give the degree of accuracy with which the time of occurrence of the shock was determined, and there is a discerpancy of slightly more than one minute between the time reported and that calculated from the seismograms.

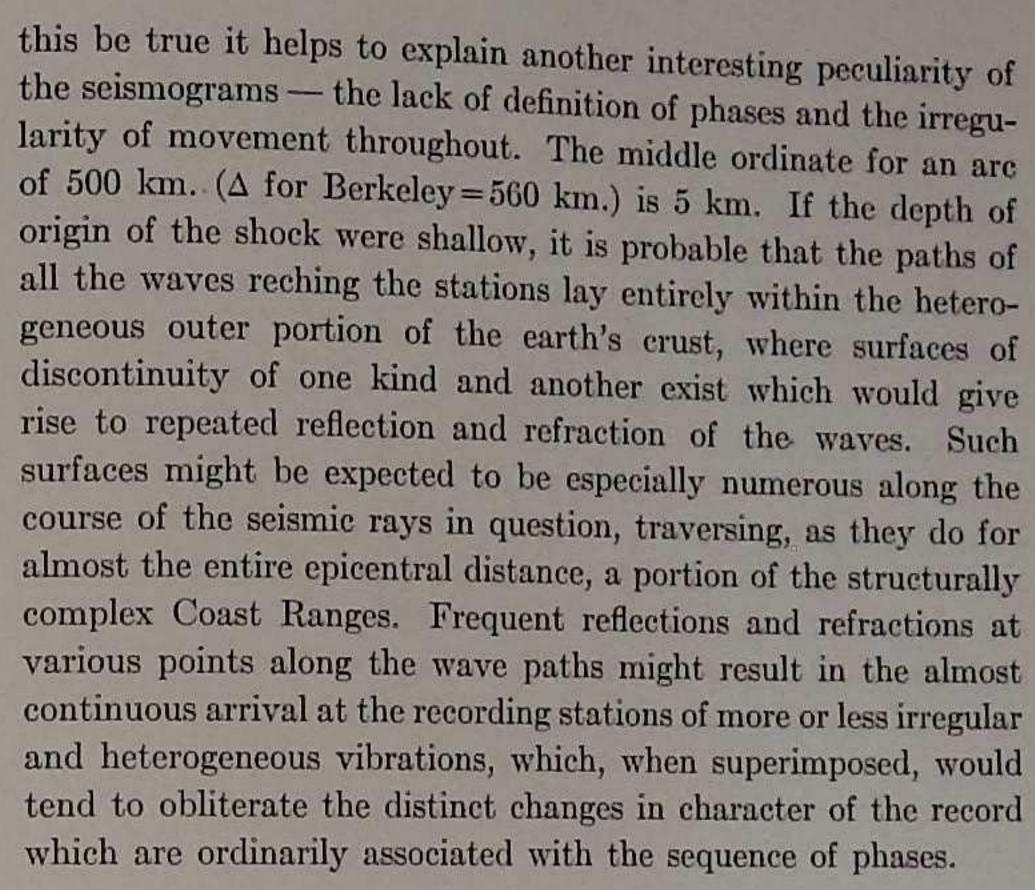

Of the Berkeley records, the vertical component sheet shows the earliest perceptible movement. A very faint emersio sets in at 2<sup>h</sup> 49<sup>m</sup> 19<sup>s</sup>. The amplitudes are exceedingly small and the period a little less than 2". At 2<sup>h</sup> 49<sup>m</sup> 37<sup>s</sup> the amplitude and the period simultaneously increase. A similar but less striking variation takes place on the N-S component record at about the same time. This occurrence is interpreted as the arrival of one of the groups of reflected or refracted waves with which the seismograms seem to abound. At 2<sup>h</sup> 50<sup>m</sup> 23<sup>s</sup> there occurs on V a further increase in period but no corresponding increase in amplitude. So poorly marked is this change that it was not detected until after a careful comparison with N-S. On the latter component there is at this time an increase in both period and amplitude, and this change

<sup>\*</sup>Bull. Seis. Soc. Amer. Vol. 10, p. 129, September, 1920.

<sup>†</sup>G. M. C. T.

of character is sufficiently pronounced to suggest that it is due to the arrival of the second preliminary tremor. 2h 50m 23s is therefore taken as the time of arrival of the S waves. The registration of the preliminary tremors on the E-W component is very unsatisfactory. The first perceptible movement is noted at 2h 49m 42s but the amplitudes remain so small, and the movement so irregular that eS can not be determined. A very pronounced increase in period and amplitude at 2h 50m 41s marks the beginning of the main phase on N-S. There is a corresponding change of character on E-W, though less striking, but on V the only variation observable is a gradual increase in period, accompanied by irregular fluctuations in amplitude, which begins before and continues after the time taken for the inception of L on the horizontal components. Two definite maxia occur on N-S, the first at 2h 51m 47s, the period being 61/2" and the amplitude 18.1 microns; the second is at 2h 52m 32s, with a displacement of 23.4 microns, the period remaining the same. Maxima on V and E-W are recorded at 2h 52m 24° and 2<sup>h</sup> 52<sup>m</sup> 25° respectively. The amplitudes are notably less than on N-S, being 10.4 microns on V, and 14.0 on E-W. The corresponding periods are 7" and 6½". Following the maxima the periods decrease somewhat, and the amplitudes wax and wane irregularly for some three minutes, after which the smaller waves of the tail portion dominate the seismogram. In general character the records of the Lick station resemble closely those described above. They show the same gradual beginning of movement and lack of definition of phases. They differ in that the period of the waves at the time of maximum displacement ranges from 2" to 5", as compared with  $6\frac{1}{2}$ " for Berkeley, and the amplitudes are notably smaller. This is particularly true of the vertical component record, which nowhere shows a displacement exceeding 3 microns, and which can not be said to possess a definite maximum.

Taber\* estimated the maximum intensity of this shock at about eight and one-half in the Rossi-Forel scale, and noted that the intensity diminished rapidly on passing outward from the epicenter. The comparatively small displacements recorded at the Lick and Berkeley stations accord with his observation and support his conclusion that the origin was of shallow depth. If

#### Teleseism of September 20, 1920.

The teleseism of September 20, 1920 was well registered at both the Berkeley and the Lick Observatory stations, except for overcrowding on the record of the vertical component at Berkeley which rendered that particular sheet illegible. The first preliminary tremor begins with a wave of condensation, as evidenced by a pronounced upward movement of the ground that is well registered on V. This phase consists of irregular waves having periods of from 21/2" to 3", upon which are superimposed minute vibrations of less than 1/2" period. The movement continues for approximately one minute, after which it dies out except for scattered, discontinuous vibrations of small amplitude. The second preliminary tremor is represented by an outstanding group of waves having periods of about 20" and comparatively large amplitudes, which contrast sharply with the diminutive movements of the preceding minutes. The interval S-P is 10' 24" for Berkeley and 10' 25" for Lick, corresponding to epicentral disstances of 9280 and 9290 km. respectively. The pronounced

<sup>\*</sup>Op. cit.

hours.

movement due to the arrival of S waves continues for two or three minutes, after which it dies away. The main phase begins with a few long waves (s=30"), slightly irregular and of small amplitude at the start. The amplitudes rapidly increase while the periods decrease to about 20", the waves at the same time becoming very smooth and sinusoidal. The maximum displacement recorded is 287 microns. It occurs on the E-W component at Berkeley. At both stations the greatest N-S displacement is notably less than that on E-W. Two maxima are found on the record of the vertical component at Berkeley, and the displacement of the ground, 245 microns in each case, is unusually large compared with the horizontal displacements. After the maxima the waves continue sinusoidal in form, but gradually decrease in amplitude, with somewhat periodic recurrences of groups of larger waves. Perceptible movement extends over approximately three
