<i>Mauritius (January 7 to April 27, 1901, Nos. 89 to 131)</i>	112

I. *General Notes on Registers from Similar Horizontal Pendulums.*

The following registers are continuous with those published by the Seismological Investigation Committee in their first three circulars and in the Reports of the British Association, 1896 to 1899.

In the next circular these registers should be continued up to December 31, 1901, and, so far as possible, supplemented by corresponding

1****

registers from the following places: Paisley, Coimbra, Beirut, Batavia, Tokio, Vizagapatam (Madras), Mauritius, Ceylon, Mexico, Swarthmore (Philadelphia), Melbourne, Sydney, West Australia, New Zealand (two stations), Cordoba (Argentina), Arequipa, Irkutsk, Tiflis, Taschkent, and Honolulu.

If observers at these and other places working with the type of instrument adopted by the British Association will kindly send a copy of their register, together with copies of their more important seismograms, to the Secretary of the Seismological Investigation Committee, British Association, Burlington House, London, W., as early as possible after June 30, and again after December 31 of each year, the interval of time which must elapse before they receive copies of the registers from co-operators in various parts of the world will be considerably reduced.

The time employed is Greenwich mean time (civil) expressed in hours, minutes, and in decimals of minutes.

D. First P.T.s.—This refers to the duration of the first preliminary tremors or the first uniform thickening of the trace.

Amplitude indicates half of the complete range of the maximum motion. When this exceeds one millimetre it is expressed in millimetres. Values less than one millimetre refer to the thickening of a line and indicate half its width.

As 1° turn of the test screw in the bed-plate of the instrument causes a tilt of 1''·9, and as this is accompanied by a measurable displacement of the outer end of the boom—it is easy to convert measurements of amplitude into seconds of arc. These latter figures are chiefly of value in connection with observations made near to earthquake origins. At a long distance from an earthquake centre the movement is practically horizontal. In other classes of investigations, as, for example, when searching for a relationship between the slow 'wanderings' of the pendulum and changes in barometric gradient, which at certain stations and under certain conditions appear to be measurable, angular measurements may be of importance.

The Register from Shide, Isle of Wight, England.
Observer, JOHN MILNE. Assistant, SHINOBU HIROTA.

[Amplitudes may be converted into angular measure by multiplying by 0''·47. Y.P. (Yarrow Pendulums) refers to records from an instrument equivalent to two Milne pendulums at right angles to each other.]

Notes on Seismograph Observations at Kew Observatory, January to July 1901.

Register No.	Notes
267	Although of long duration the amplitude of the swings was not large. A rather long interval between the first and second maximum phases, the swings being more pronounced at the second phase.

Register from the Liverpool Observatory, Bidston, England—continued.

From January to April inclusive a three component Rebeur-Ehler pendulum in Strassburg recorded 59 earthquakes. Only 19 of these which are the first nineteen in the preceding register were noted by a Milne pendulum in the same building, whilst 30 out of the 59 were recorded by similar instruments in England. From this it may be inferred that 50 per cent. of the Strassburg records are common to Great Britain.

The Register from Toronto, Canada. Director, Professor R. F. STUPART.
